## **DFS / Topological Ordering**

## **Depth First Search**

Follow the first path you find as far as you can go; back up to last unexplored edge when you reach a dead end, then go as far you can

Naturally implemented using recursive calls or a stack

## DFS(s) – Recursive version

Global Initialization: mark all vertices undiscovered

DFS(v) Mark v discovered

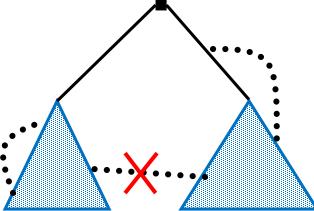

> for each edge {v,x} if (x is undiscovered) Mark x discovered DFS(x)

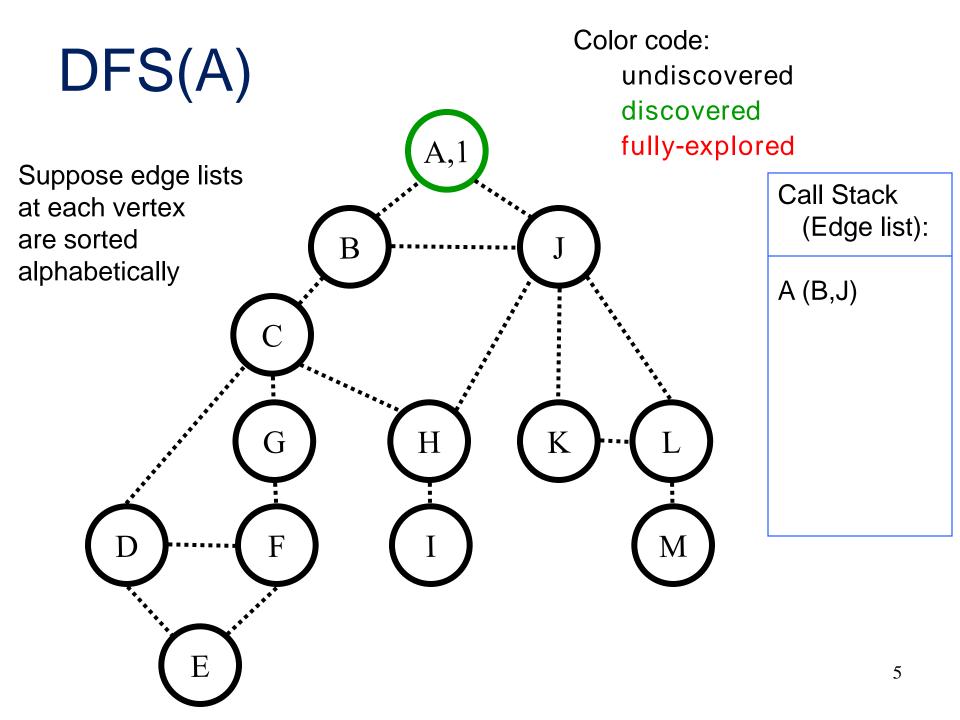

Mark v full-discovered

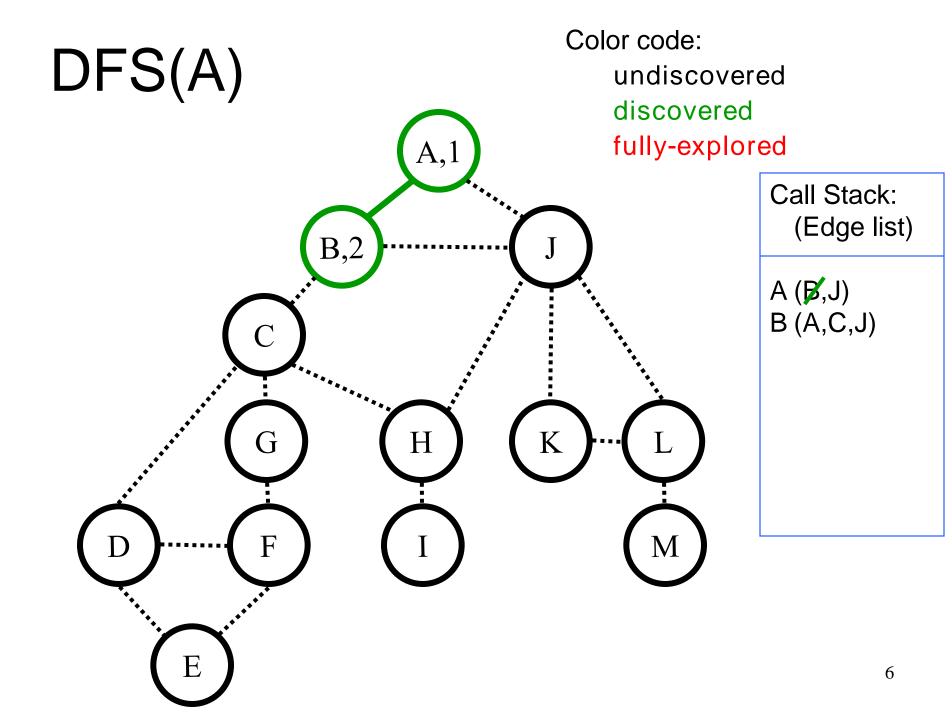

## Non-Tree Edges in DFS

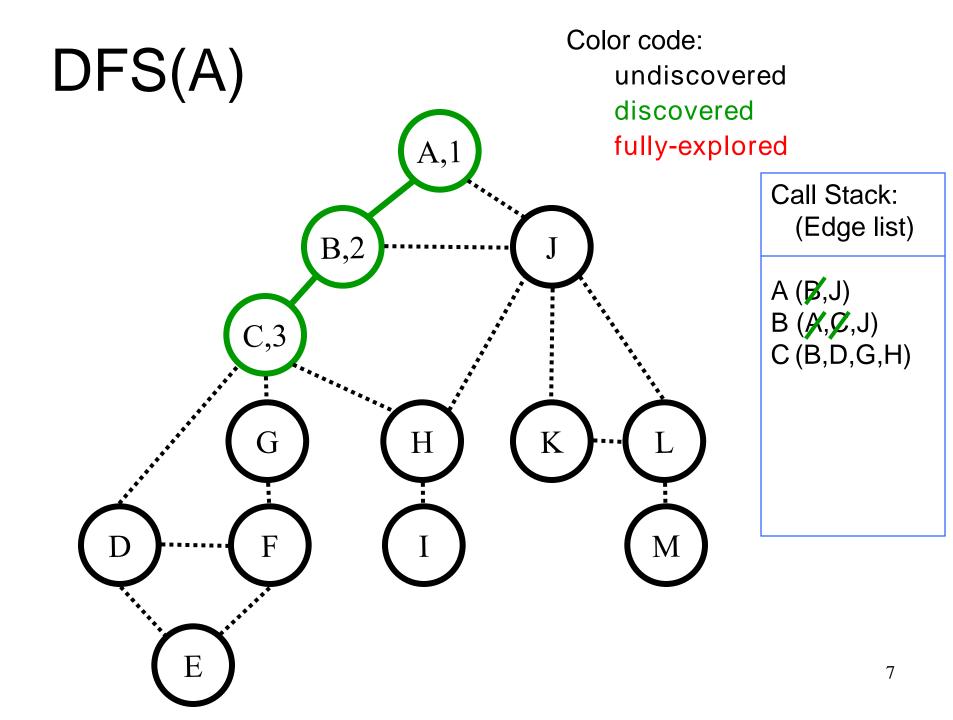

All non-tree edges join a vertex and one of its descendents/ancestors in the DFS tree

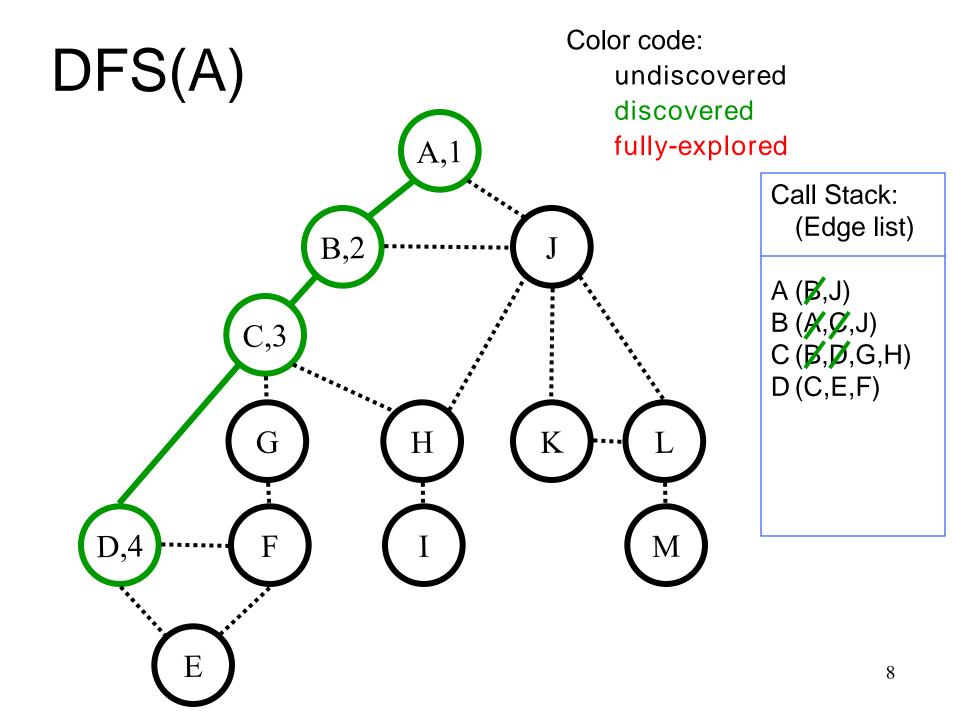

BFS tree  $\neq$  DFS tree, but, as with BFS, DFS has found a tree in the graph s.t. non-tree edges are "simple" – only descendant/ancestor

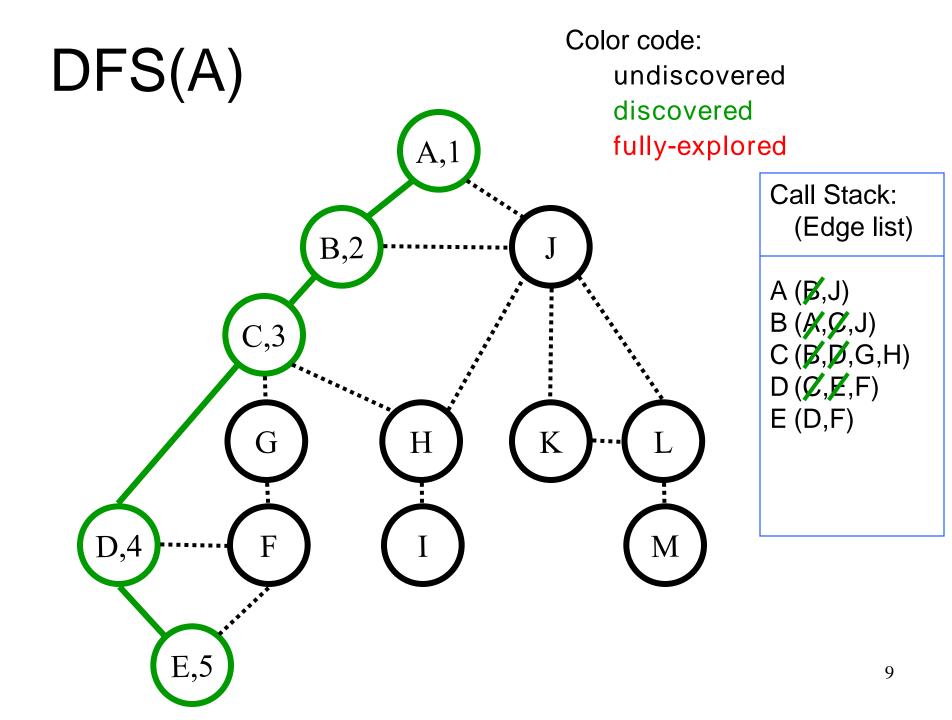

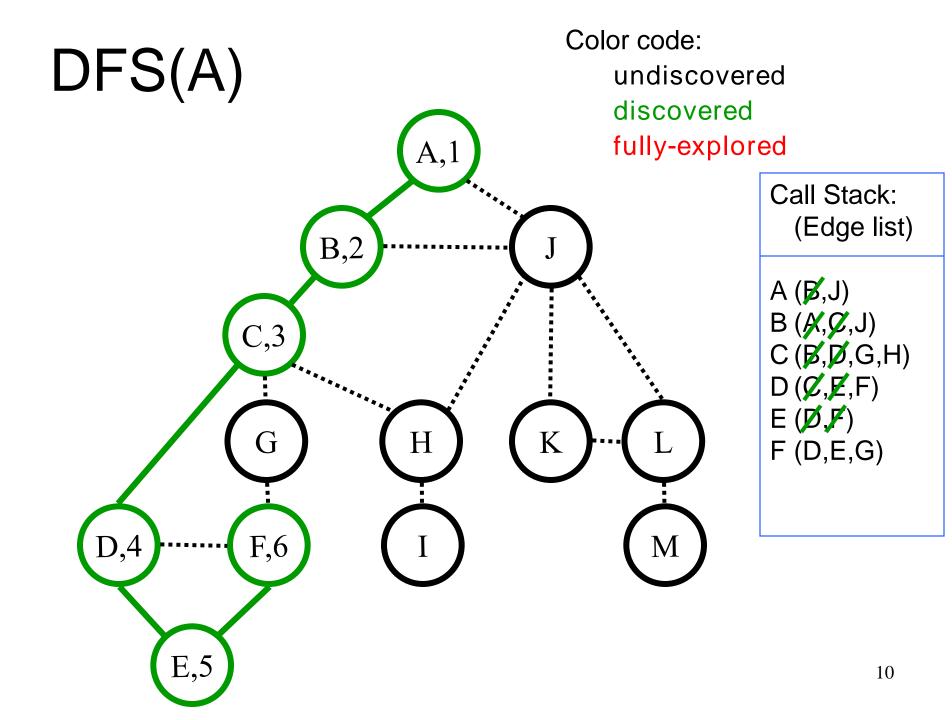

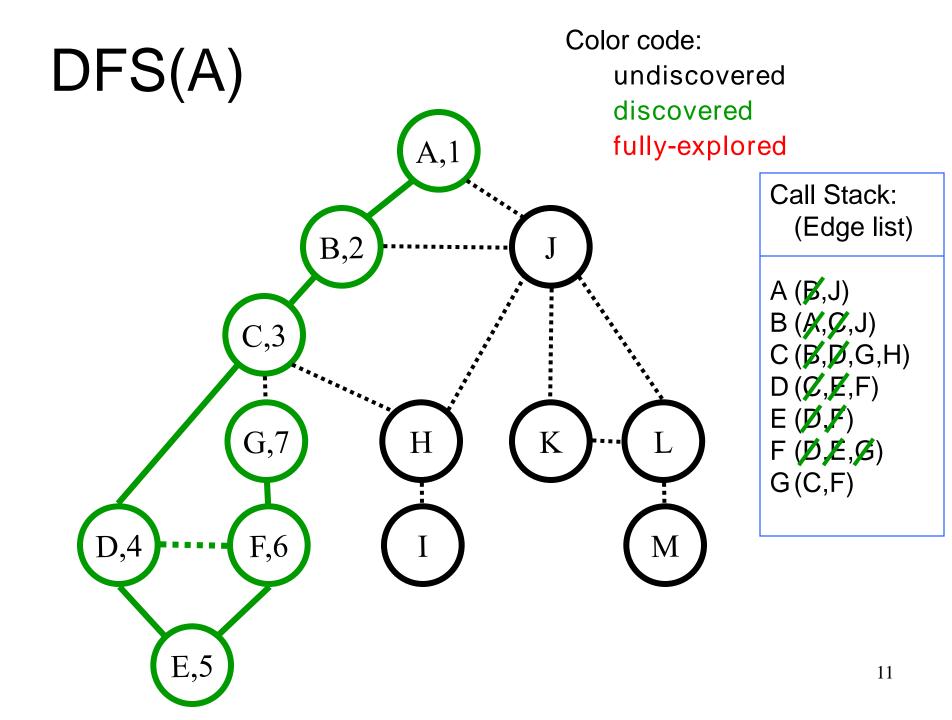

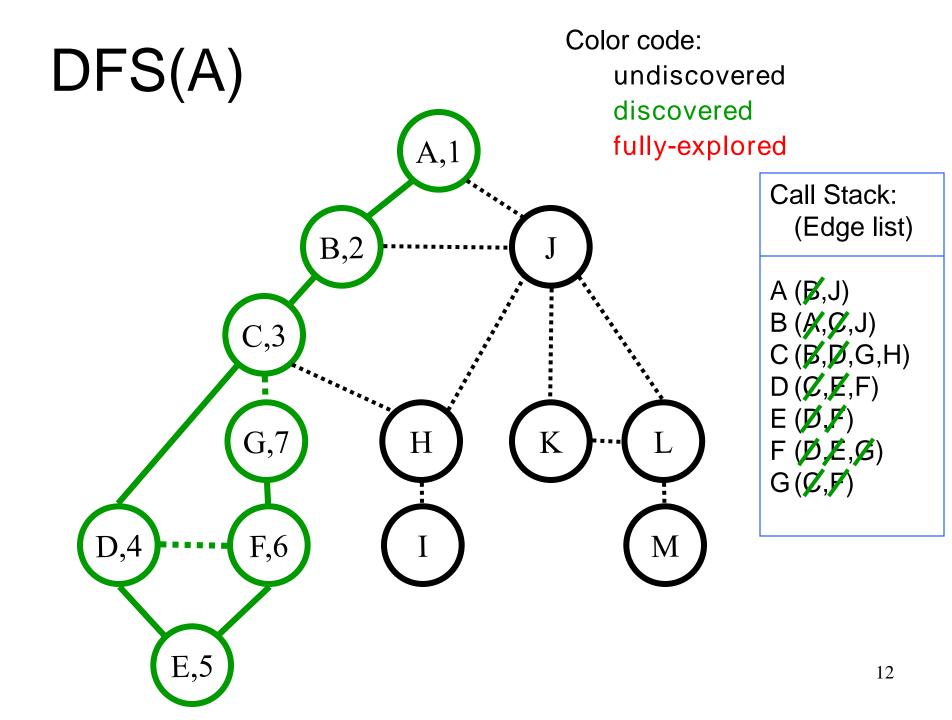

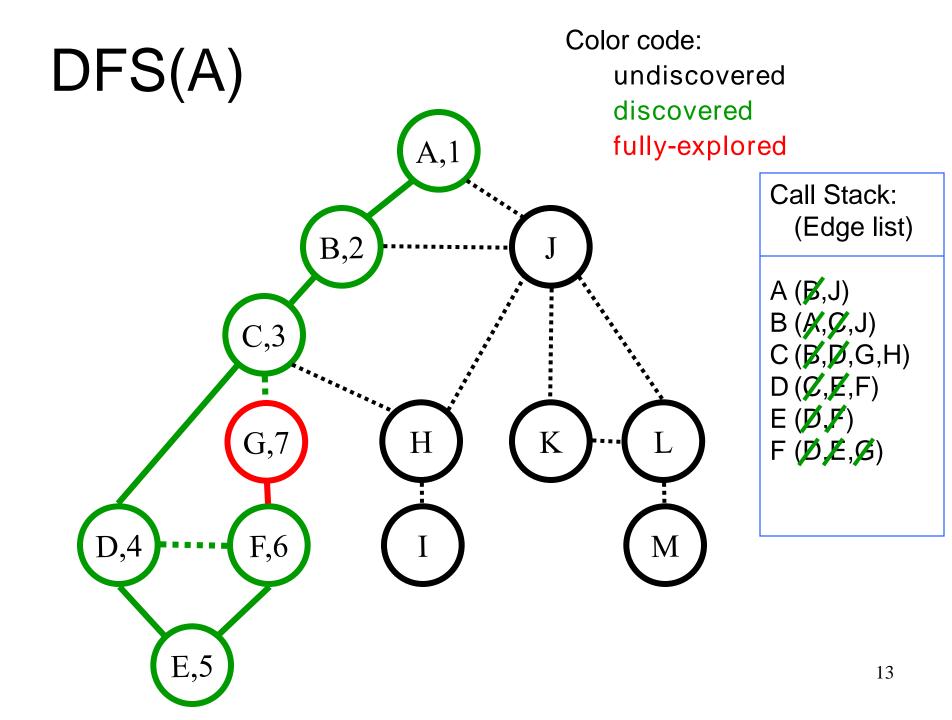

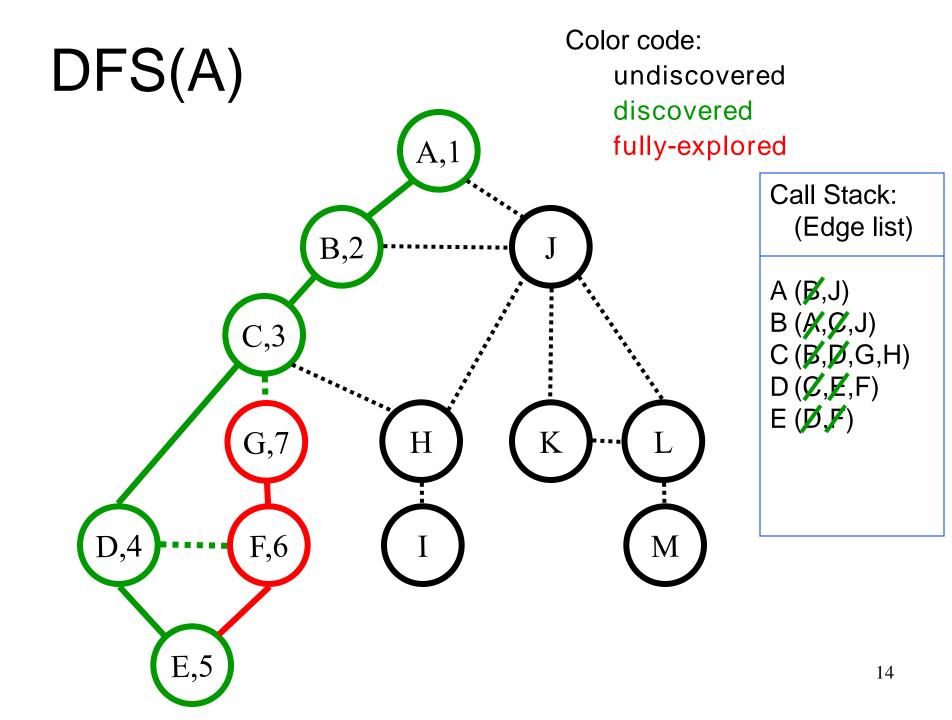

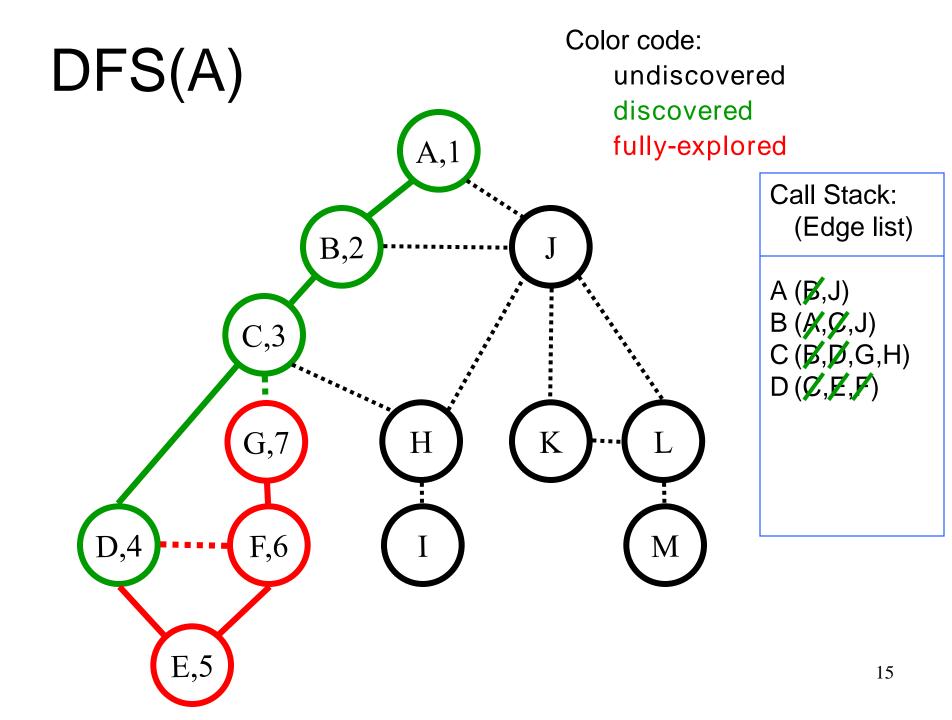

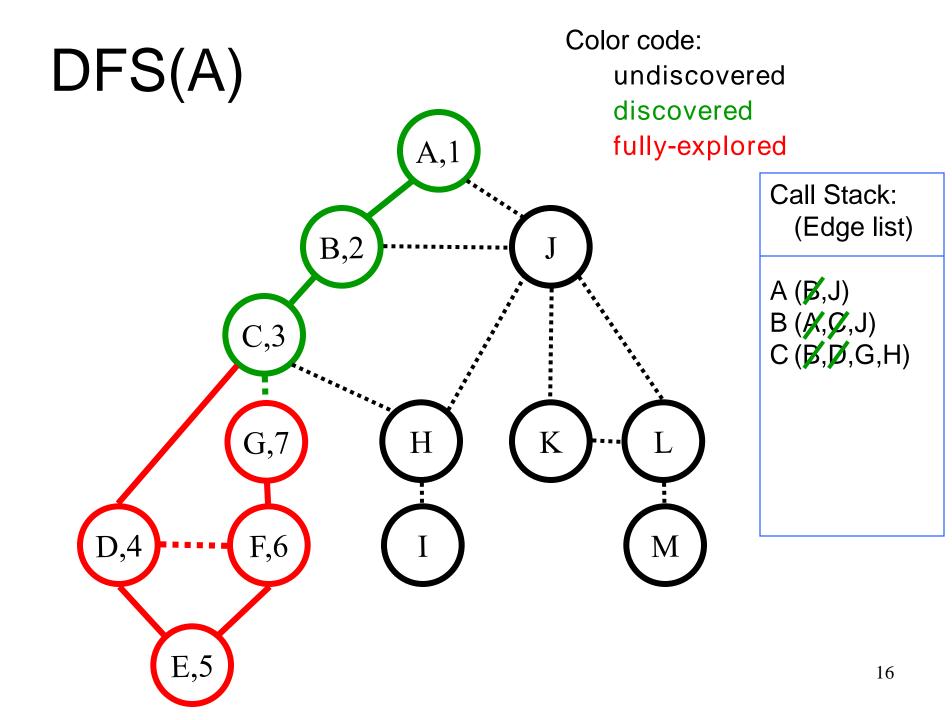

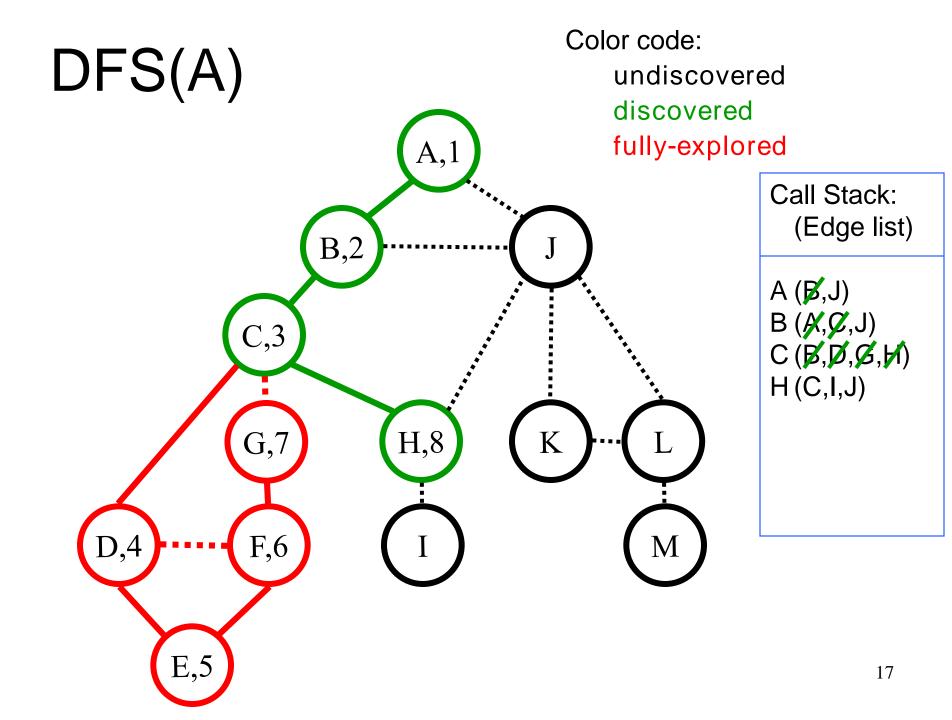

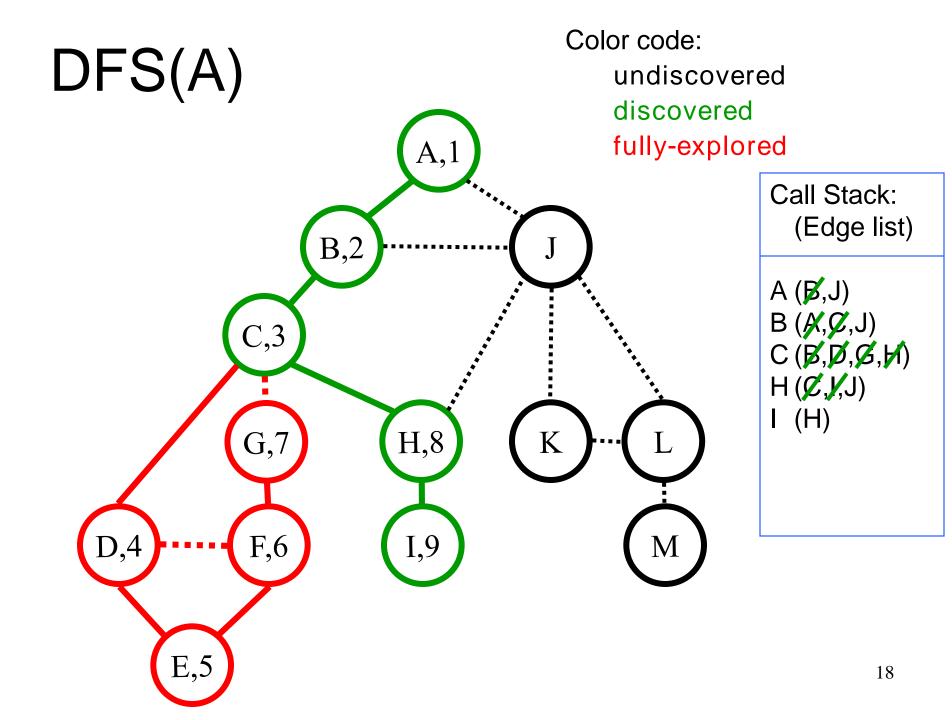

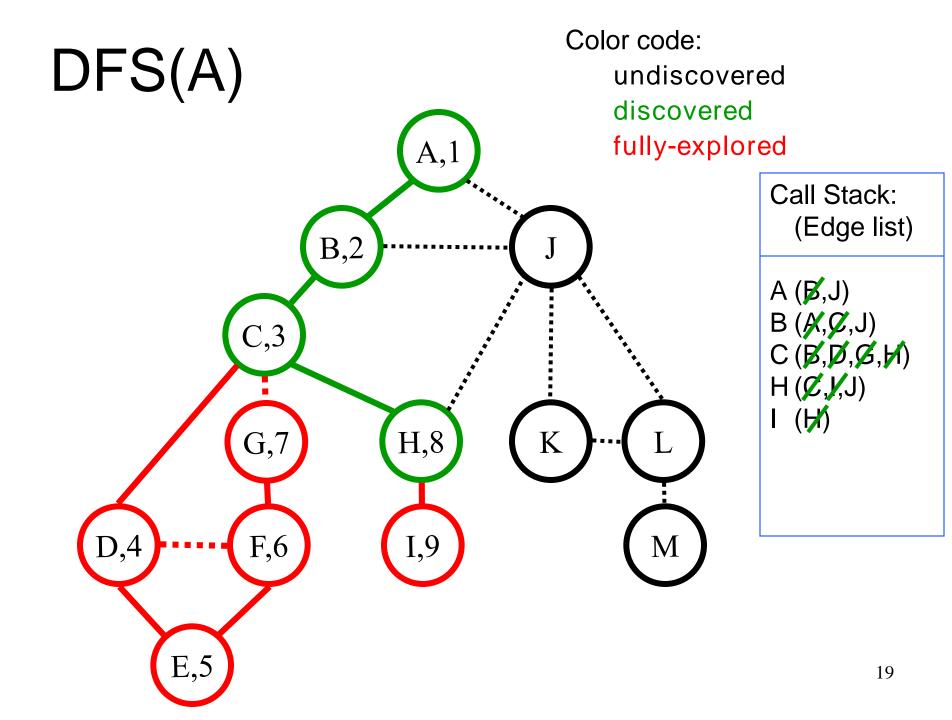

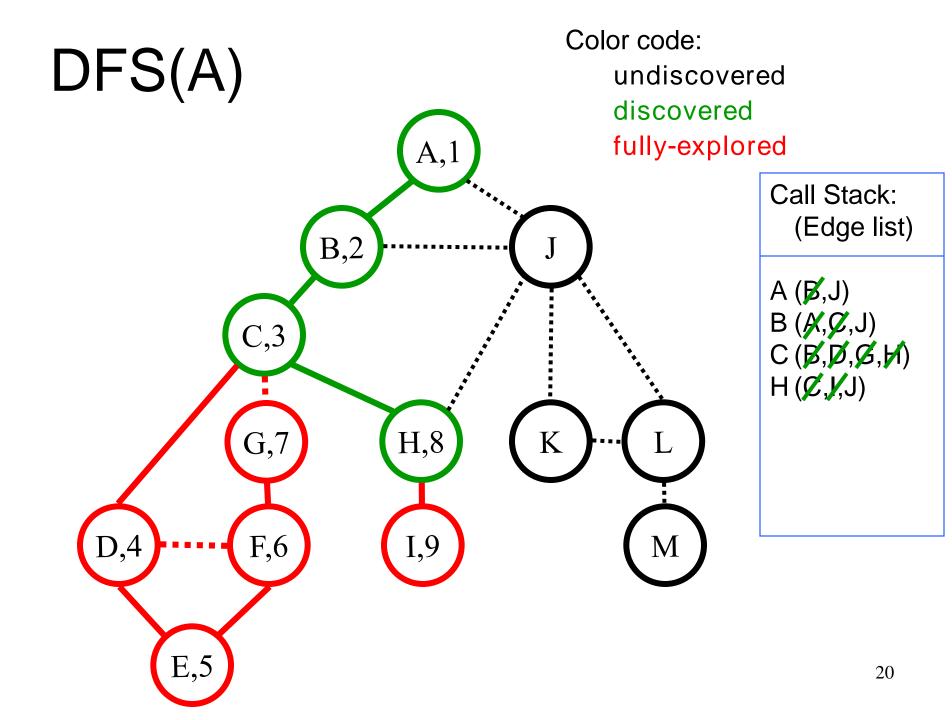

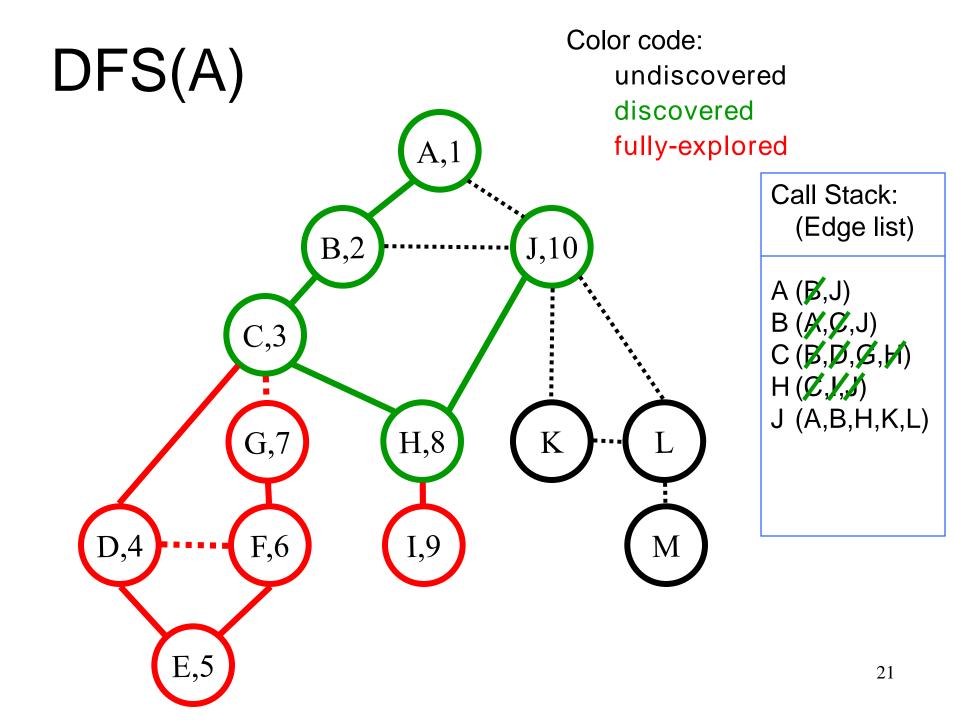

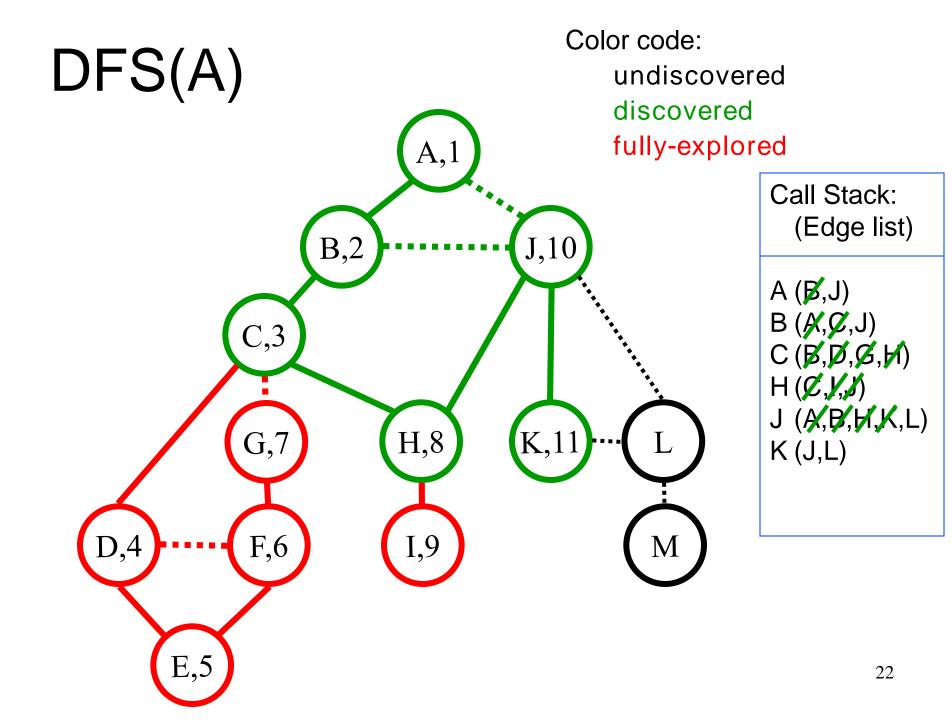

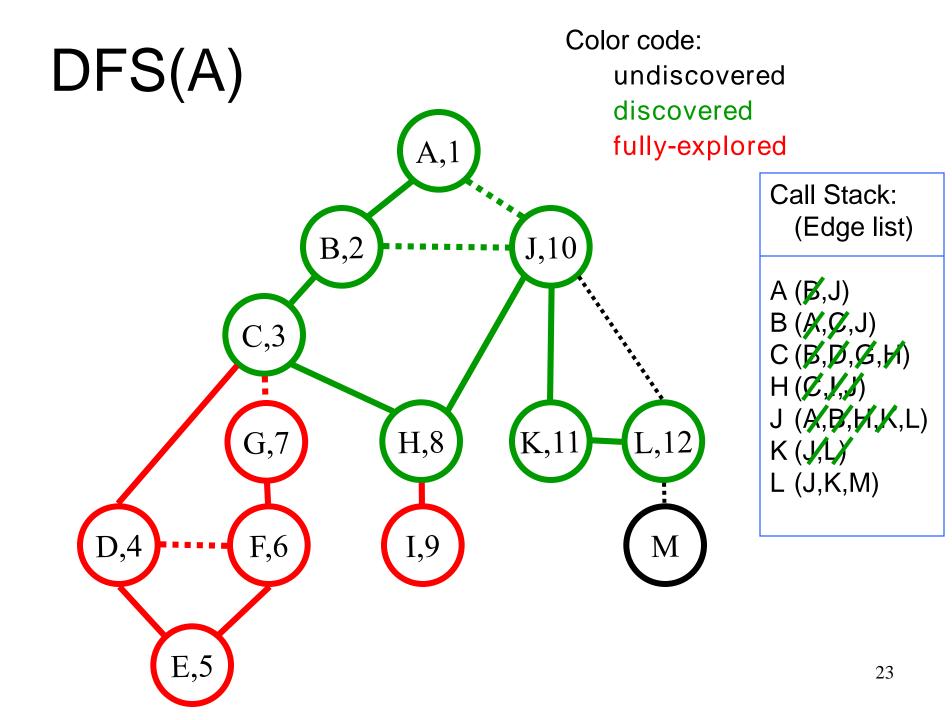

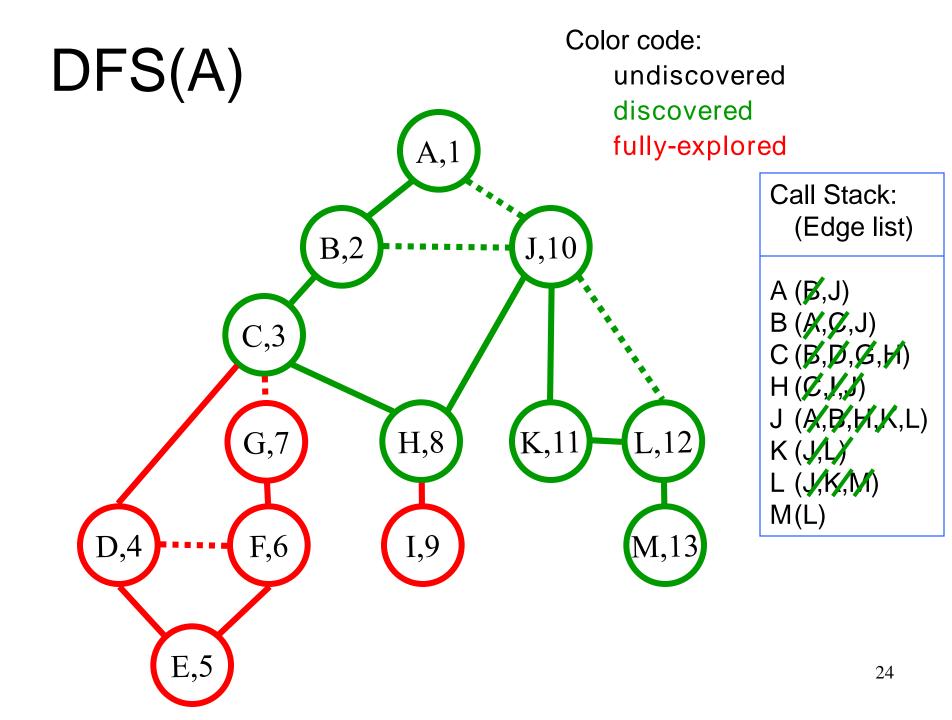

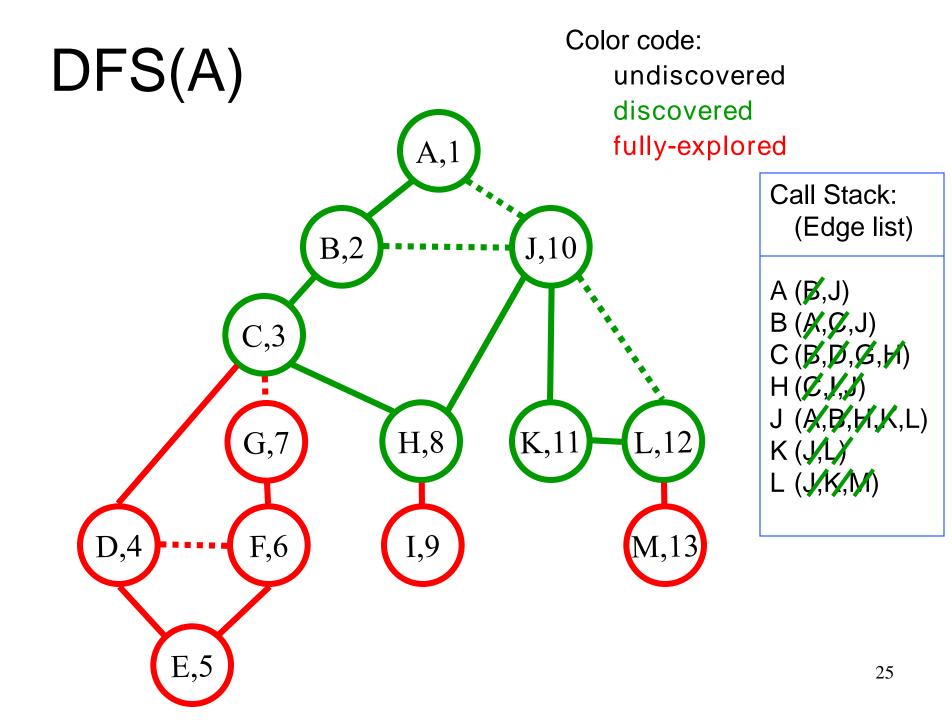

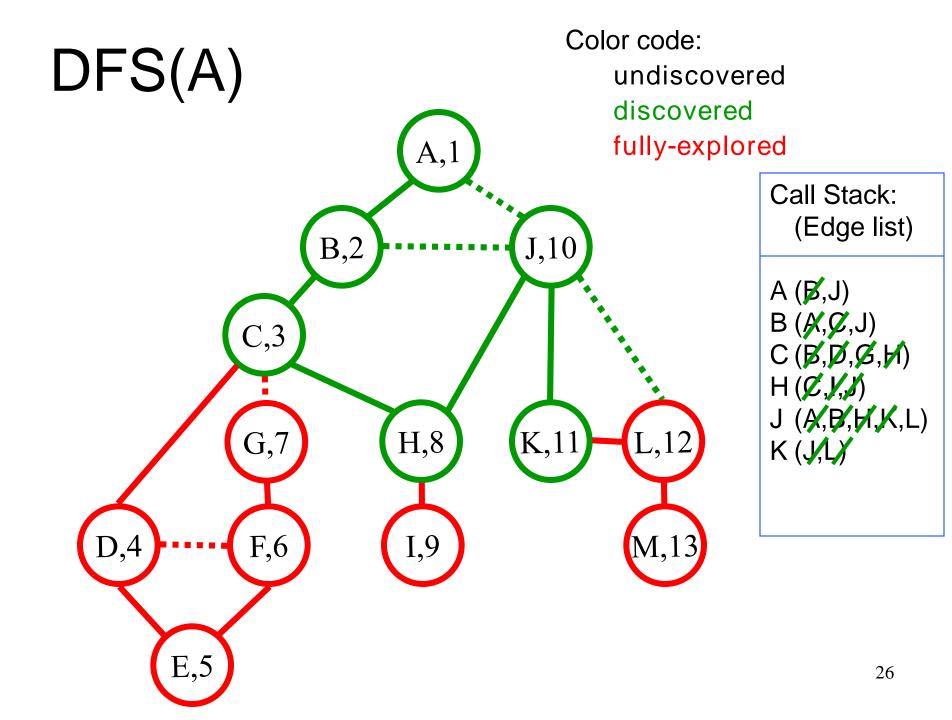

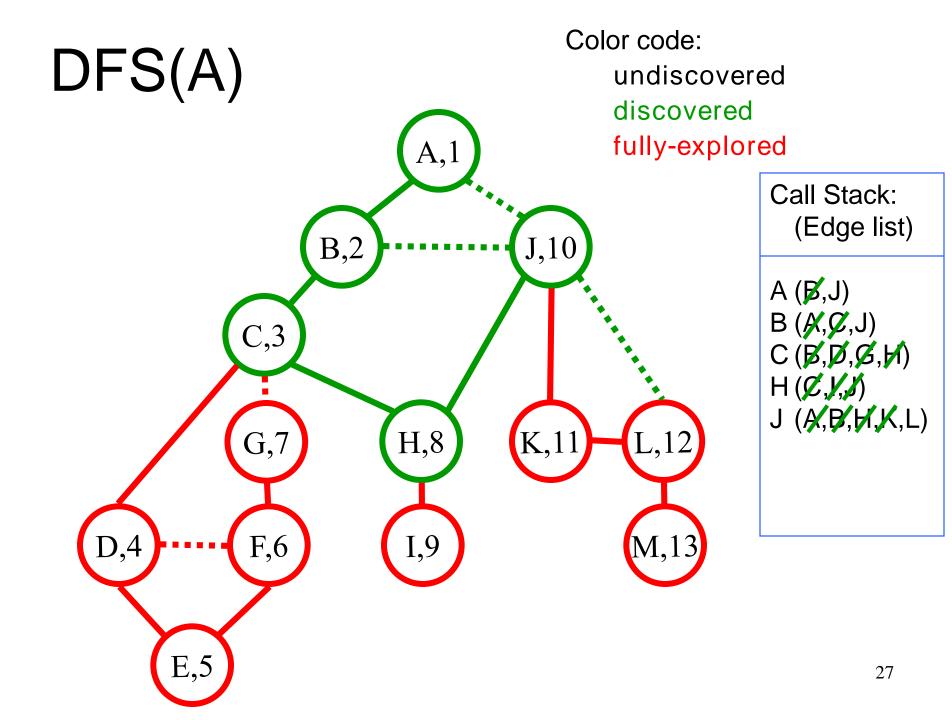

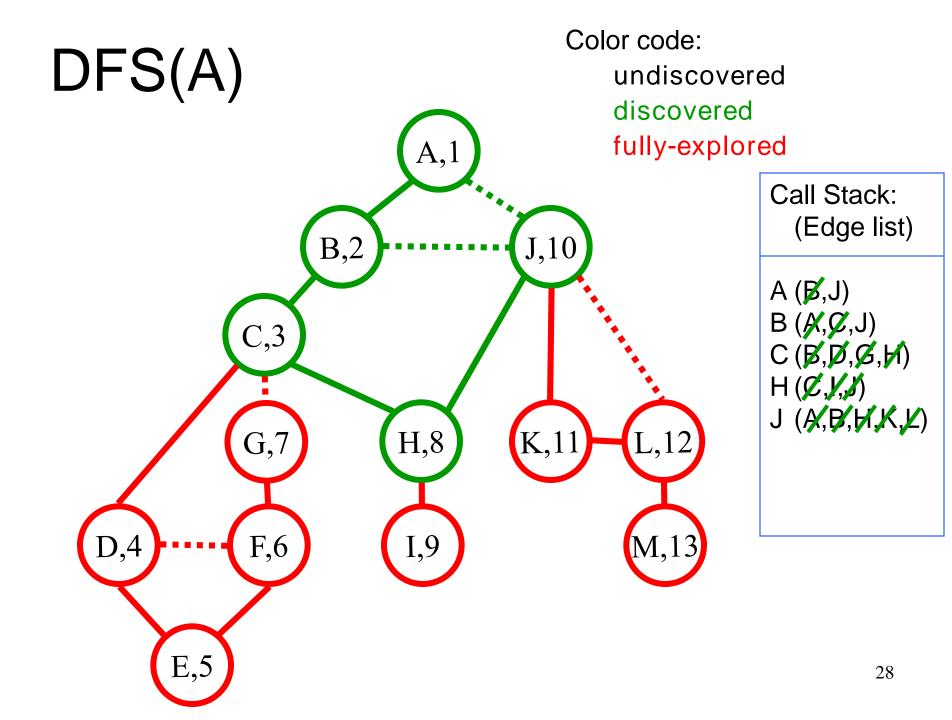

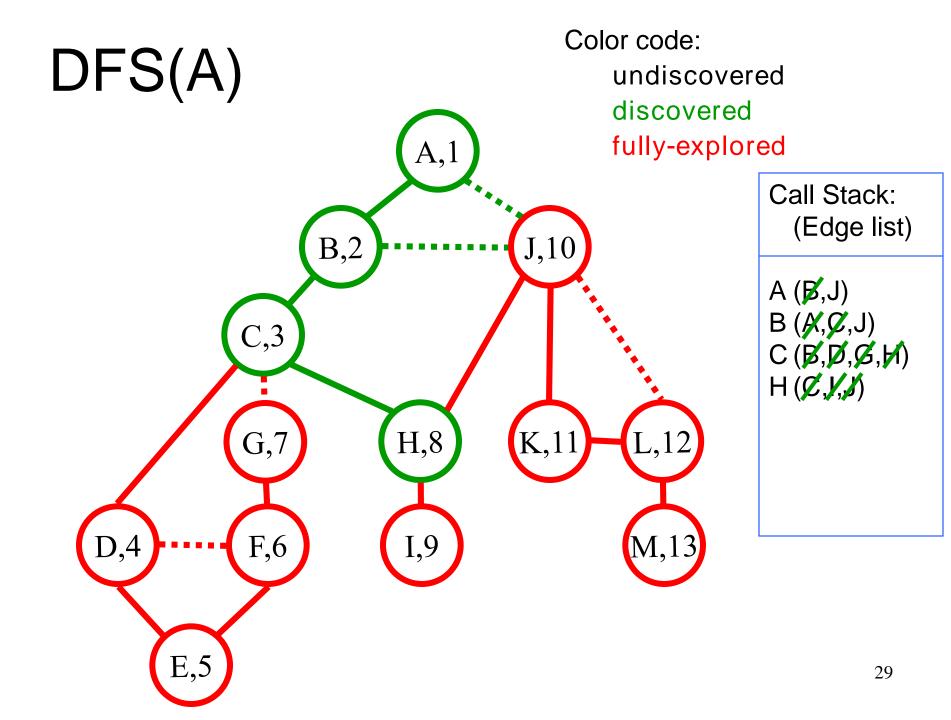

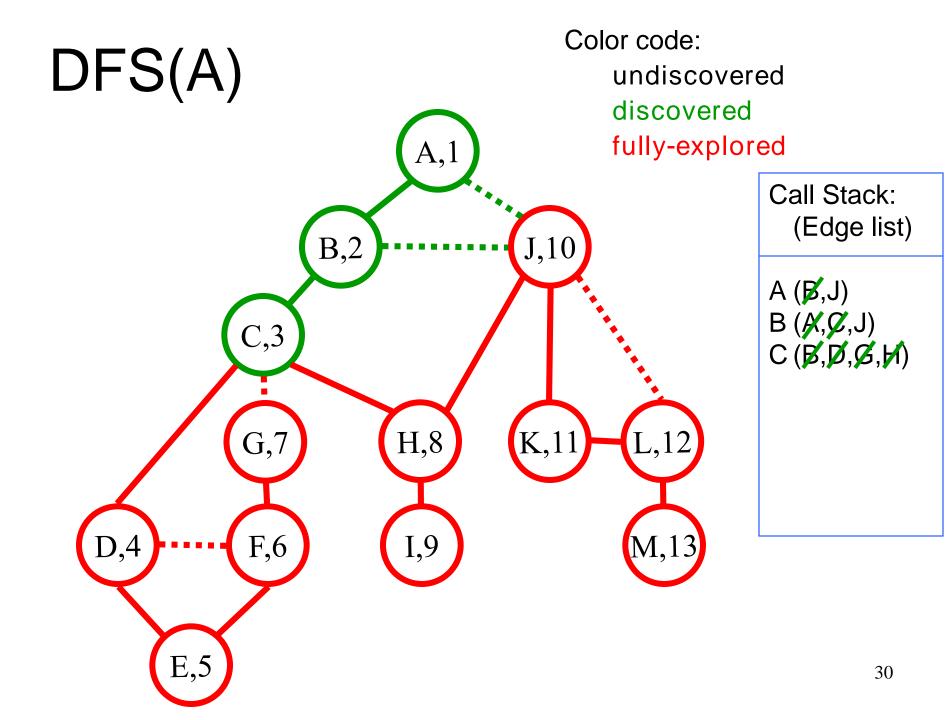

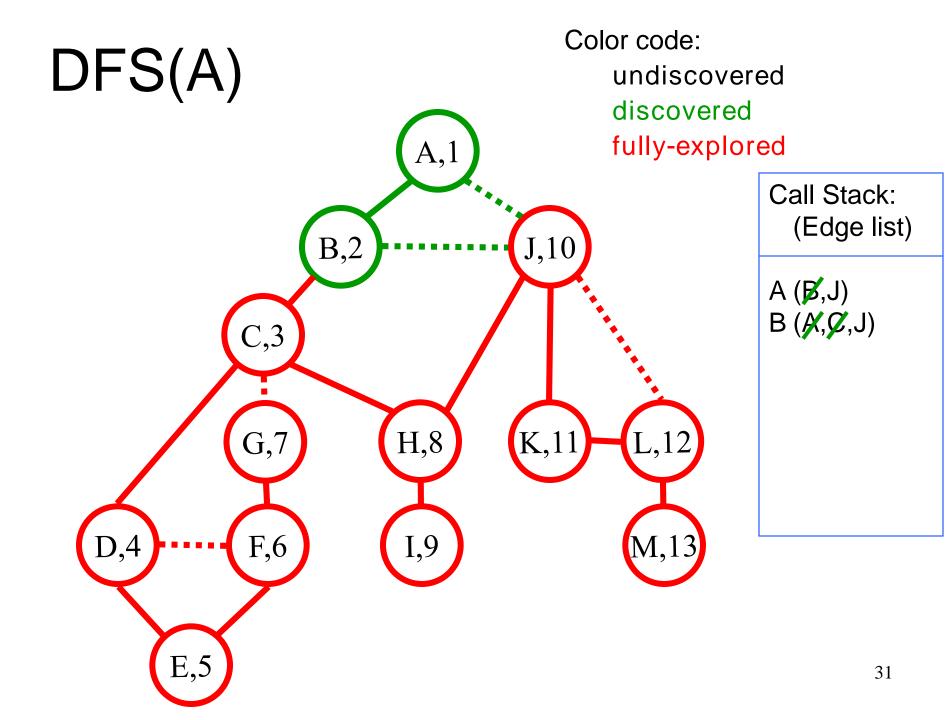

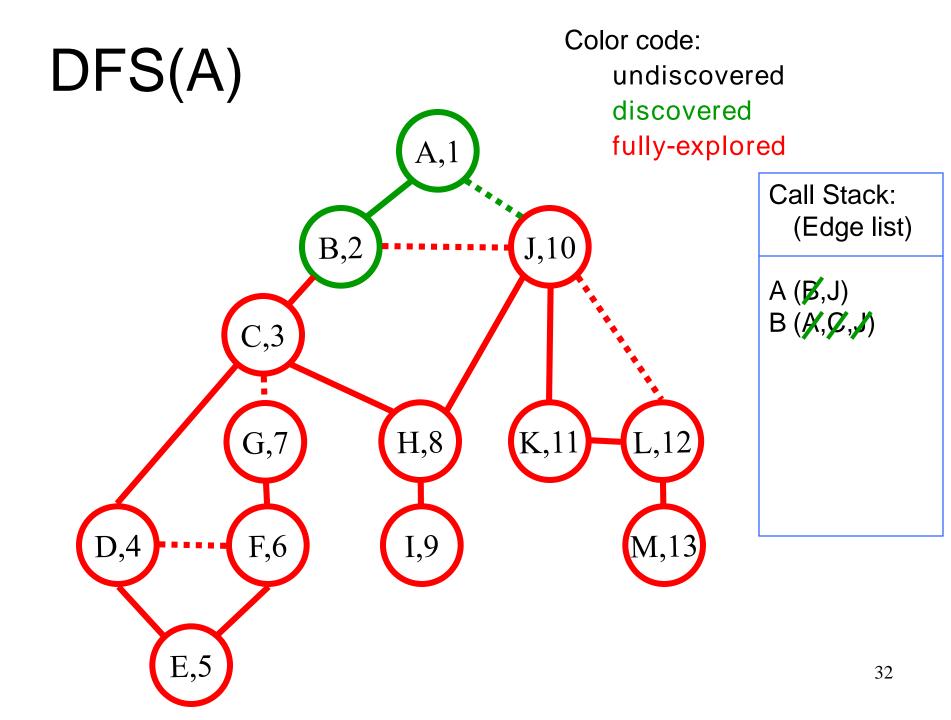

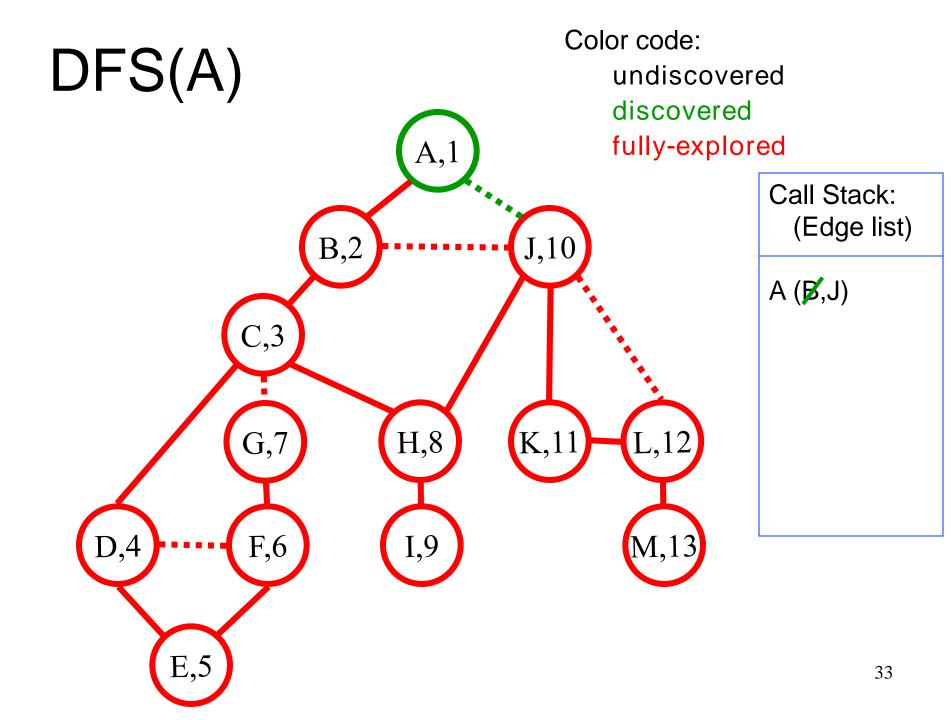

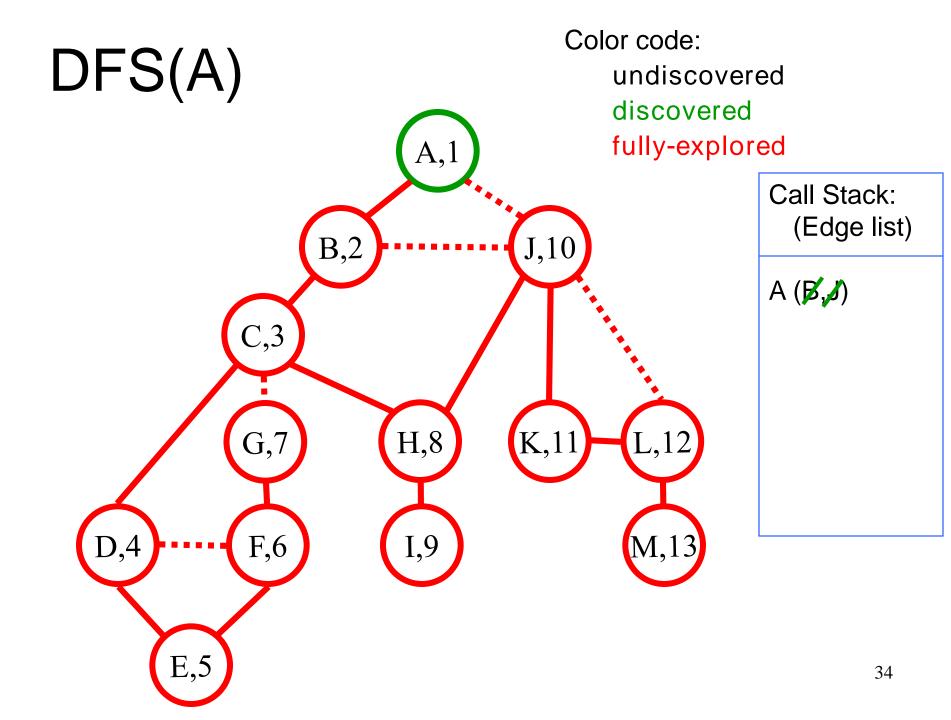

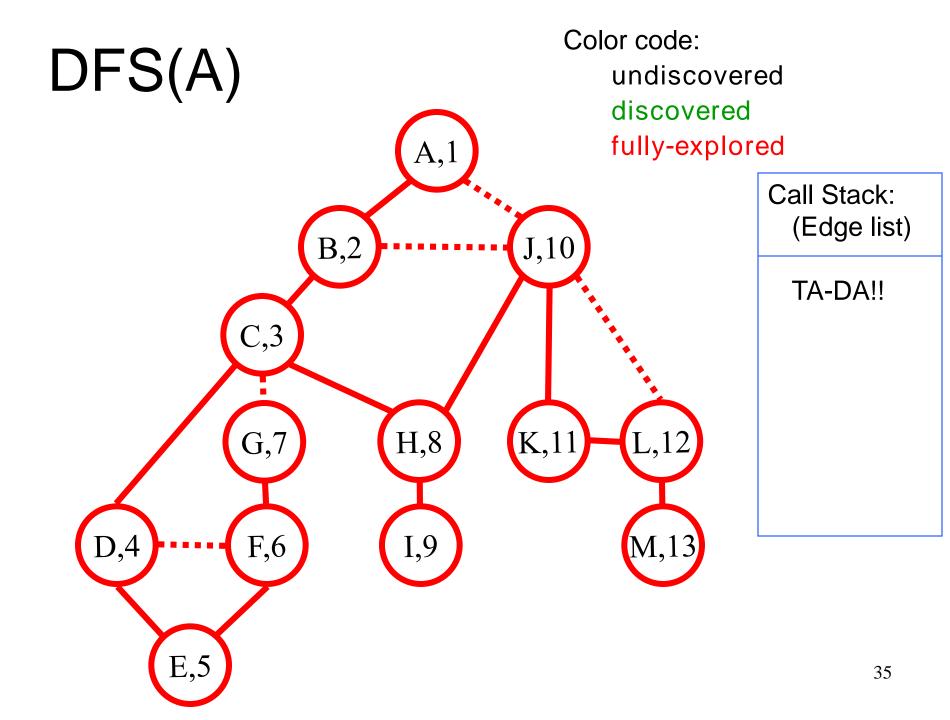

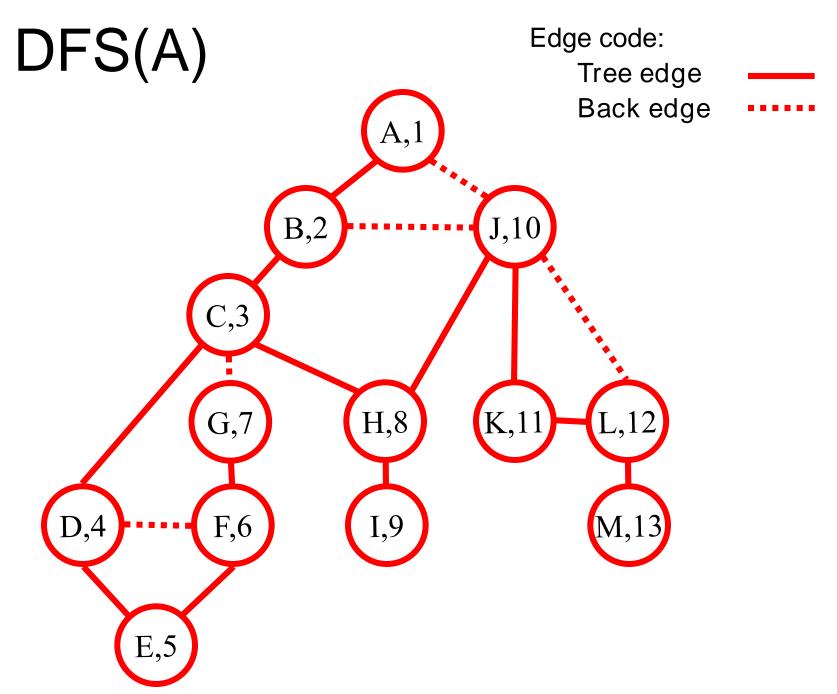

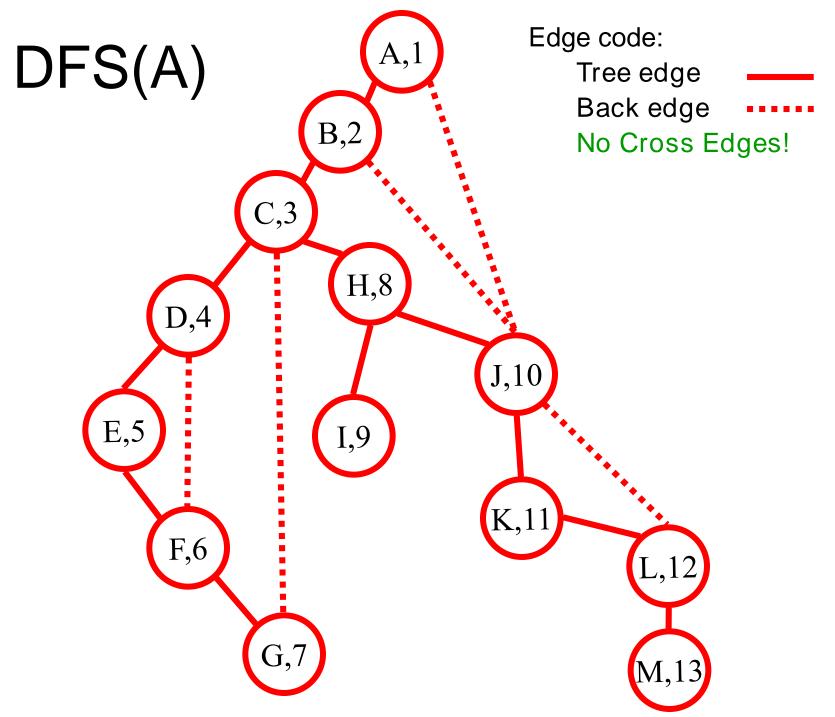

## Properties of (undirected) DFS

#### Like BFS(s):

- DFS(s) visits x iff there is a path in G from s to x
   So, we can use DFS to find connected components
- Edges into then-undiscovered vertices define a tree the "depth first spanning tree" of G

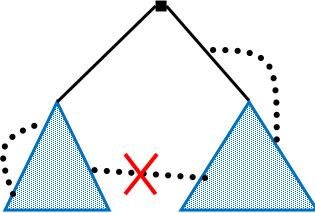

#### Unlike the BFS tree:

- The DF spanning tree isn't minimum depth
- Its levels don't reflect min distance from the root
- Non-tree edges never join vertices on the same or adjacent levels

### Non-Tree Edges in DFS

All non-tree edges join a vertex and one of its descendents/ancestors in the DFS tree

BFS tree  $\neq$  DFS tree, but, as with BFS, DFS has found a tree in the graph s.t. non-tree edges are "simple" – only descendant/ancestor

## Non-Tree Edges in DFS

Lemma: During DFS(x) every vertex marked visited is a descendant of x in the DFS tree

Lemma: For every edge  $\{x, y\}$ , if  $\{x, y\}$  is not in DFS tree, then one of x or y is an ancestor of the other in the tree.

#### Proof:

One of x or y is visited first, suppose WLOG that x is visited first and therefore DFS(x) was called before DFS(y)

Since  $\{x, y\}$  is not in DFS tree, y was visited when the edge  $\{x, y\}$  was examined during DFS(x)

Therefore y was visited during the call to DFS(x) so y is a descendant of x.

#### DAGs and Topological Ordering

42

#### **Precedence Constraints**

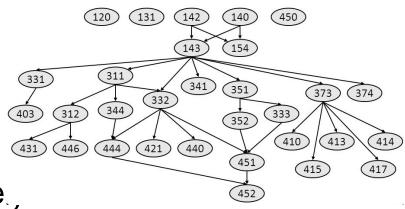

In a directed graph, an edge (i, j) means task *i* must occur before task *j*.

Applications

- Course prerequisite:
   course *i* must be taken before *j*
- Compilation:

must compile module *i* before.

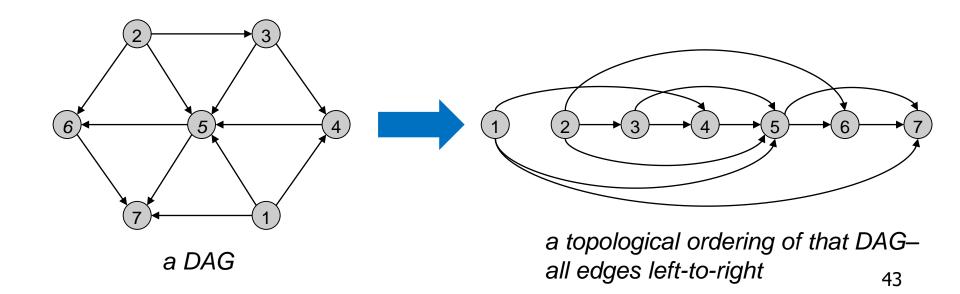

- Computing overflow:
   output of job *i* is part of input to job *j*
- Manufacturing or assembly: sand it before paint it

#### Directed Acyclic Graphs (DAG)

A DAG is a directed acyclic graph, i.e., one that contains no directed cycles.

**Def**: A topological order of a directed graph G = (V, E) is an ordering of its nodes as  $v_1, v_2, ..., v_n$  so that for every edge  $(v_i, v_j)$  we have i < j.

#### **DAGs: A Sufficient Condition**

Lemma: If G has a topological order, then G is a DAG.

Pf. (by contradiction)

Suppose that G has a topological order 1, 2, ..., n and that G also has a directed cycle C.

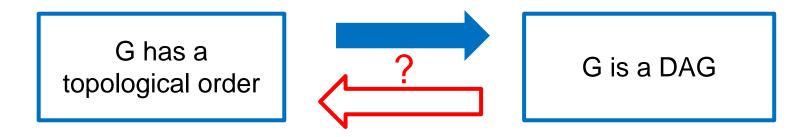

Let *i* be the lowest-indexed node in C, and let *j* be the node just before *i*; thus (j,i) is an (directed) edge.

By our choice of *i*, we have i < j.

On the other hand, since (j, i) is an edge and 1, ..., n is a topological order, we must have j < i, a contradiction

the directed cycle C

#### **DAGs: A Sufficient Condition**

## Every DAG has a source node

Lemma: If G is a DAG, then G has a node with no incoming edges (i.e., a source).

Pf. (by contradiction)

Suppose that G is a DAG and and it has no source

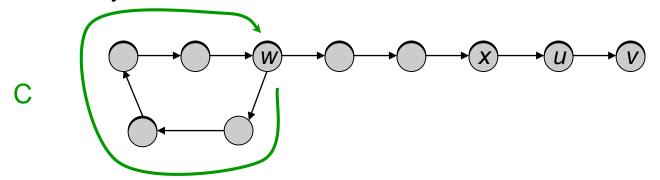

Pick any node v, and begin following edges backward from v. Since v has at least one incoming edge (u, v) we can walk backward to u.

Then, since u has at least one incoming edge (x, u), we can walk backward to x.

Repeat until we visit a node, say w, twice.

Is this similar to a previous proof?

Let C be the sequence of nodes encountered between successive visits to w. C is a cycle.

# DAG => Topological Order

Lemma: If G is a DAG, then G has a topological order

```
Pf. (by induction on n)
Base case: true if n = 1.
```

IH: Every DAG with n-1 vertices has a topological ordering.

**IS**: Given DAG with n > 1 nodes, find a source node v.

 $G - \{v\}$  is a DAG, since deleting v cannot create cycles.

Reminder: Always remove vertices/edges to use IH

By IH,  $G - \{v\}$  has a topological ordering.

Place v first in topological ordering; then append nodes of G - { v }

in topological order. This is valid since v has no incoming edges.

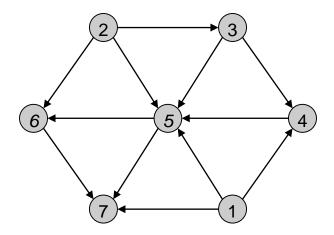

#### A Characterization of DAGs

G has a topological order

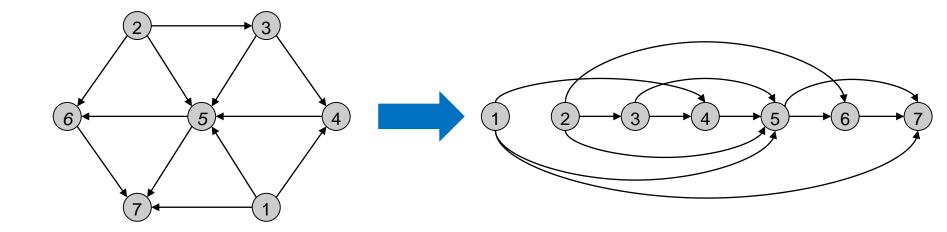

G is a DAG

#### Topological Order Algorithm: Example

#### Topological Order Algorithm: Example

Topological order: 1, 2, 3, 4, 5, 6, 7

# **Topological Sorting Algorithm**

#### Maintain the following:

count[w] = (remaining) number of incoming edges to node w

S = set of (remaining) nodes with no incoming edges

Initialization:

count[w] = 0 for all w

count[w]++ for all edges (v,w)

 $S = S \cup \{w\}$  for all w with count[w]=0

Main loop:

while S not empty

- remove some v from S
- make v next in topo order
- for all edges from v to some w –decrement count[w]
  - -add w to S if count[w] hits 0

Correctness: clear, I hope

Time: O(m + n) (assuming edge-list representation of graph)

O(1) per node O(1) per edge

O(m + n)

#### Summary

- Graphs: abstract relationships among pairs of objects
- Terminology: node/vertex/vertices, edges, paths, multi-edges, self-loops, connected
- Representation: Adjacency list, adjacency matrix
- Nodes vs Edges: m = O(n<sup>2</sup>), often less
- BFS: Layers, queue, shortest paths, all edges go to same or adjacent layer
- DFS: recursion/stack; all edges ancestor/descendant
- Algorithms: Connected Comp, bipartiteness, topological sort
